

A Generative model does not store objects, data from a distribution in memory, to then retrieve upon query. Instead it distills a distribution into its weights which allow it to *generate* the distribution.

Instilling weights in a generative model is (ideally) an approach toward a shorter and more elegant Description of the distribution, *taking advantage of the non-randomness* of the distribution, rather than storing the data itself (which is how you *must* store a random distribution). If the weights can be so tuned, there are inevitable gains in compression/representation/description.

You are learning to replicate the source, which intrinsically contains the characteristics of the output distribution, instead of trying to store the distribution (the source's output) itself. The data is there upon request, but needn't be there in constant residence. Why store a textbook if you have a genie who can recite it for you word for word?

In this sense, the data-on-request-algorithm/replicated-source is a superposition of the data, residing in the form of shards in a probabilistic algorithm (a latent distribution!). When you want an observation, it will be generated (sampled!).

Quantum particles seem to similarly be embodiments of distributions. When you must observe where things are, they fall in line, however when you do not need to know the raw data of the system, it is a compressed superposition of *what is likely to happen*. The distribution instilled in these particles is not a constant fact, it just continues to express itself when needed. Our physics is dependent on the emissions of these generators. We *obey the word of God as expressed through a prophet*, not *God himself*.

Quantum computing aims to *juice the lemon of superposition* by encoding problems into the information-compressors that are quantum particles. Might we transport our massive Transformers—stages for superposed probabilities to interfere in structured anticipation of observation—into real systems of superposed interference and observe them? Gaussian distributions (any of your liking) can be approximated by mixtures of other Gaussian distributions...

After all, the distributions which govern the behavior of your mind (expressed in your words and actions) are composed as an algorithmic mixture of smaller physical systems with intrinsic distributions.
